# Introduction

## Cosmic-rays (CRs)

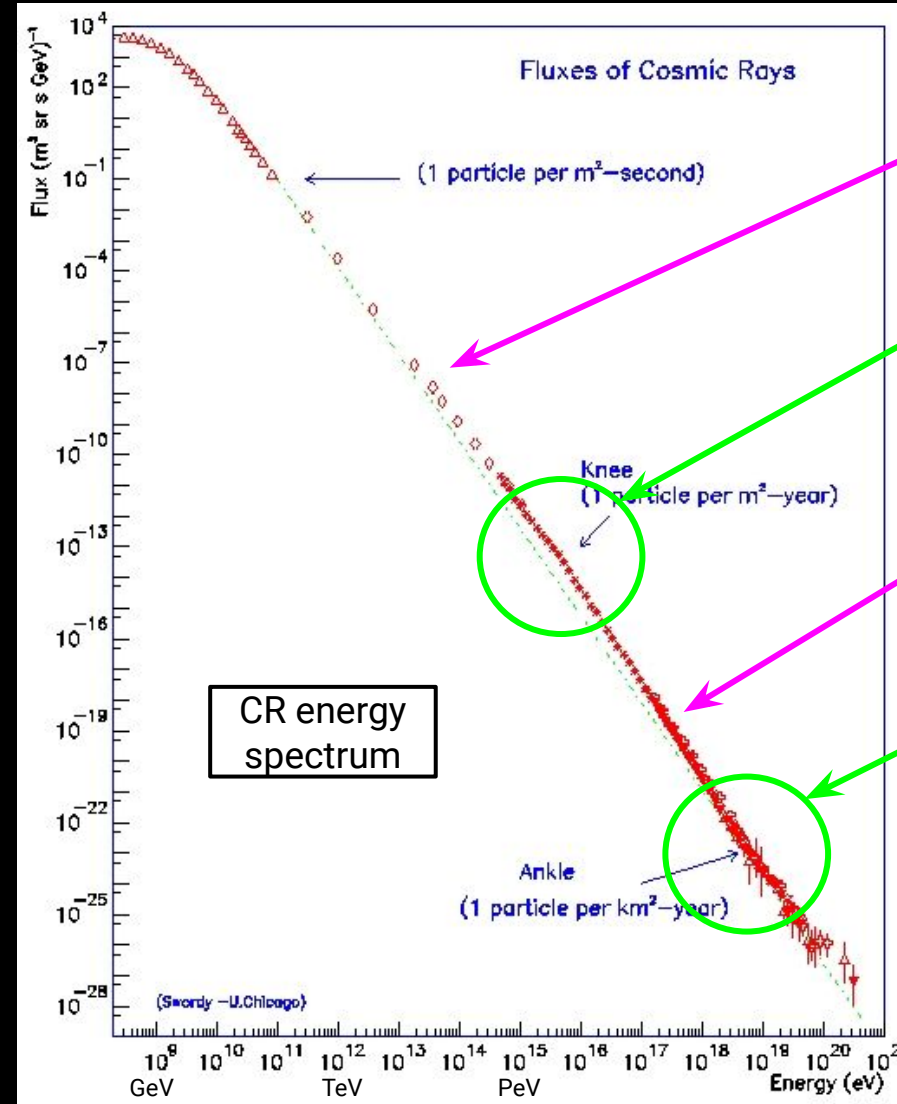

$$\text{Power Law} \\ dN/dE \propto E^{-\gamma}$$

### Cosmic-ray particles:

- ★ high-energy ionized nuclei (~90% protons + 9% alpha + heavy nuclei)
- ★ mostly relativistic
- ★ very few of them have ultra-relativistic energies up to  $10^{20}$  eV

### Fundamental questions of CR physics:

- 1) Where do they come from?
- 2) How are they accelerated to such high energies?
- 3) What is their impact on the ISM?

power law  $E^{-2.7}$

CR "knee"

power law  $E^{-3}$

CR "ankle"

# Introduction

## Interstellar medium (ISM)

- ★ Interstellar medium (ISM)
  - 99% of the mass = gas
    - 90% H + 9% He + 1% C, N, O, etc.
  - 1% of the mass = grains
- ★ Dense molecular clouds
  - density: from  $10^4$  to  $10^7$  cm $^{-3}$
  - temperature: from 8 to 20 K
- ★ Chemical reactions:
  - in gas phase
  - on the grain surfaces

- ★ **Cosmic-rays:** ionization → ISM molecular complexity  
→ ionization of H<sub>2</sub> (most abundant molecule) ⇒ H<sub>2</sub> cosmic-ray **ionization rate  $\zeta$**  (s $^{-1}$ )

# Scientific context

## Studied region: the HB3/W3 complex

- \* Location:  $\sim 2$  kpc in the northern constellation Cassiopeia, in the Heart Nebula
- \* W3: giant molecular cloud and HII region containing a very active factory of massive stars
- \* HB3 (G132.7+1.3): Supernova Remnant. Its south eastern part is adjacent to W3 (Digel et al. 1996)
- \* Age of the SNR:  $\sim 20$ -30 kyr
- \* Explosion energy:  $\sim 10^{51}$  erg

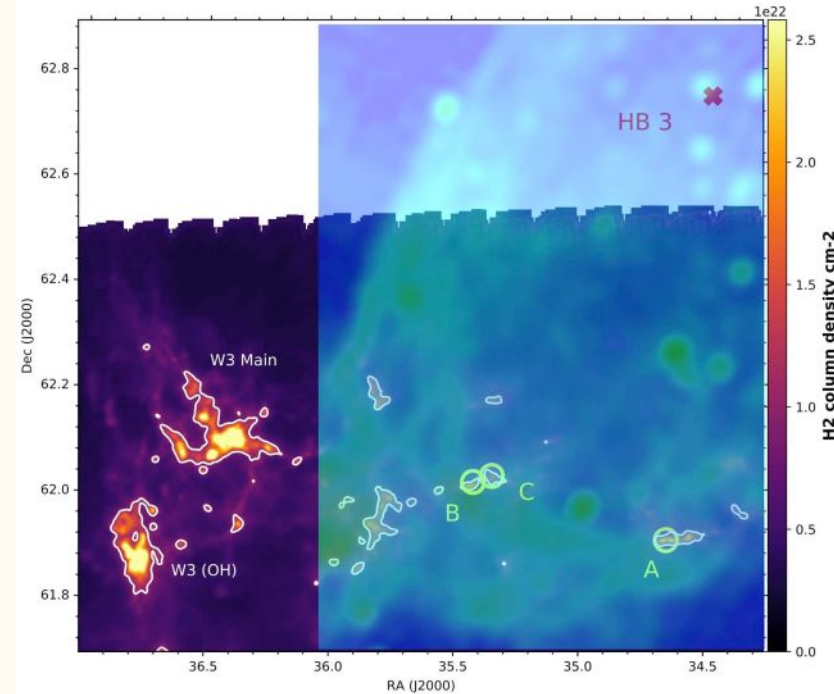

The Heart Nebula

# Context

## Astrochemistry - Cosmic-rays (CRs)

- ★ Cosmic-rays: ionization → impact on the chemistry  
→ H<sub>2</sub> ionization rate  $\zeta$  (s<sup>-1</sup>) : typical value  $\zeta_{\text{H}_2} = \sim 10^{-17} \text{ s}^{-1}$
- ★ Goal: use several direct and indirect chemical tracers of the ionization in order to constrain the CR ionization rate in the HB3/W3 complex to better understand the processes responsible for the acceleration and propagation of CRs in the Galaxy
- ★ Chemical modeling with Nautilus: identification of the most sensitive species to the ionization rate  $\zeta$ 
  - ★ Radio observations:
    - 2 campaigns already done with the IRAM 30m before the beginning of my PhD (single pointings)
    - 1 with the Yebes 40m in 2022 (P. I., single pointings)
    - 1 with the IRAM 30m in 2024 (P. I., on-the-fly map)

Yebes 40m

IRAM 30m

on A and B

# Methods

## 3-phase Nautilus gas-grain model (Ruaud et al. 2016, Wakelam et al. 2024)

- ★ Nautilus uses:
    - 1141 chemical species, including 548 on the grains
    - different types of reactions:
      - in the gas phase, on the grain surfaces and gas-grain interactions
  - ★ Based on the resolution of chemical kinetics differential equations
  - ★ Computes the gas and ice composition as a function of time for a set of physical conditions (such as  $T_{\text{gas}}$ ,  $T_{\text{dust}}$ ,  $A_V$ ,  $n_H$ ,  $\zeta$ ), either static or time-dependent, starting from an initial gas-phase composition
- ⇒ Outputs: time-dependent abundances of the molecules (gas + ice)

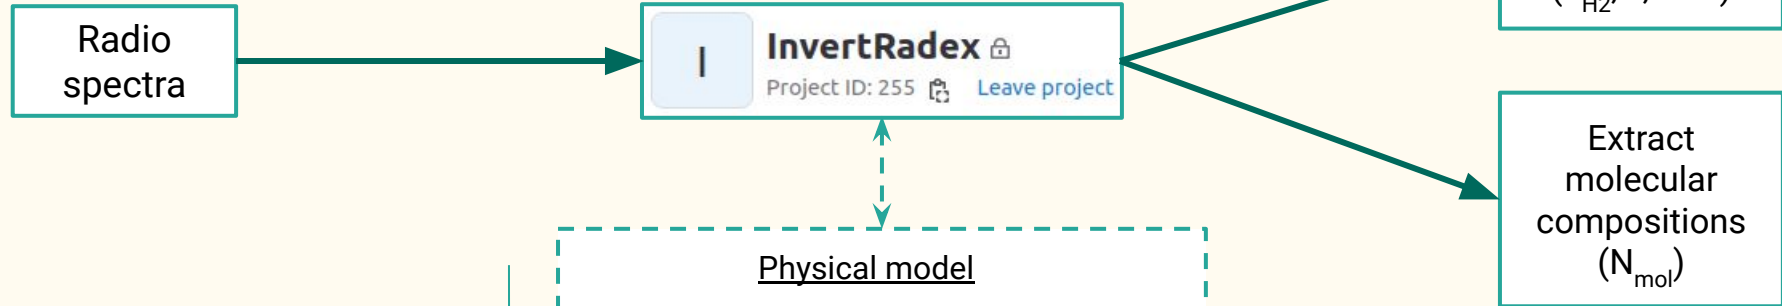

Goal: reproduce the observed molecular column densities to constrain  $\zeta$

Developed at the LAB by  
Valentine Wakelam

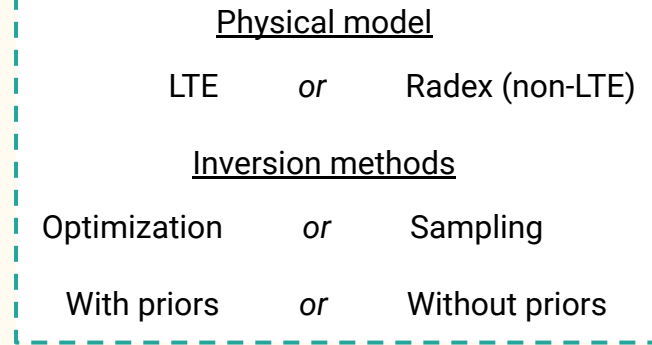

# Methods

## Extract parameters from radio data: InvertSpectra code

\* Preliminary analysis of the 30m observations on HC<sub>3</sub>N indicates that both sources A and B are:

- quite dense ( $n_{\text{H}_2} > 3 \times 10^5 \text{ cm}^{-3}$ )
- cold ( $T < 13 \text{ K}$ )

\* Physical parameters determined for HC<sub>3</sub>N then used as prior distributions to help the fit for the other species

→ allows to extract  $N_{\text{mol}}$  for all the molecules in LTE + in Radex when the collision rates are available

# Results

## Comparison of the molecular abundances

Abundances of the molecules extracted from the IRAM 30m, in non-LTE when the collision rates are available, or in LTE if not. The **bold** font is used for species presenting optically thick lines.

- \* 38 molecules detected, including some isotopologues in the 30m data
- \* Comparison with TMC-1: very similar for some species (SO, N<sub>2</sub>H<sup>+</sup>, etc.), very different for others (HC<sub>3</sub>N, CCS, etc.)

# Constraining $\zeta_{\text{H}_2}$ with chemistry?

## Using Nautilus and simulated data

---

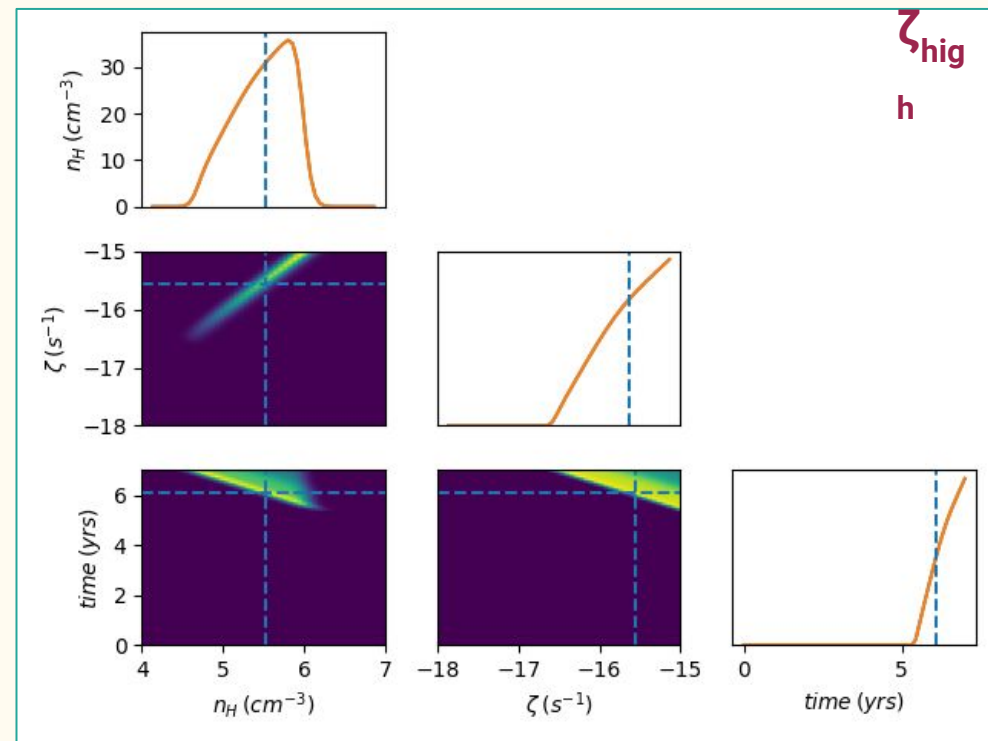

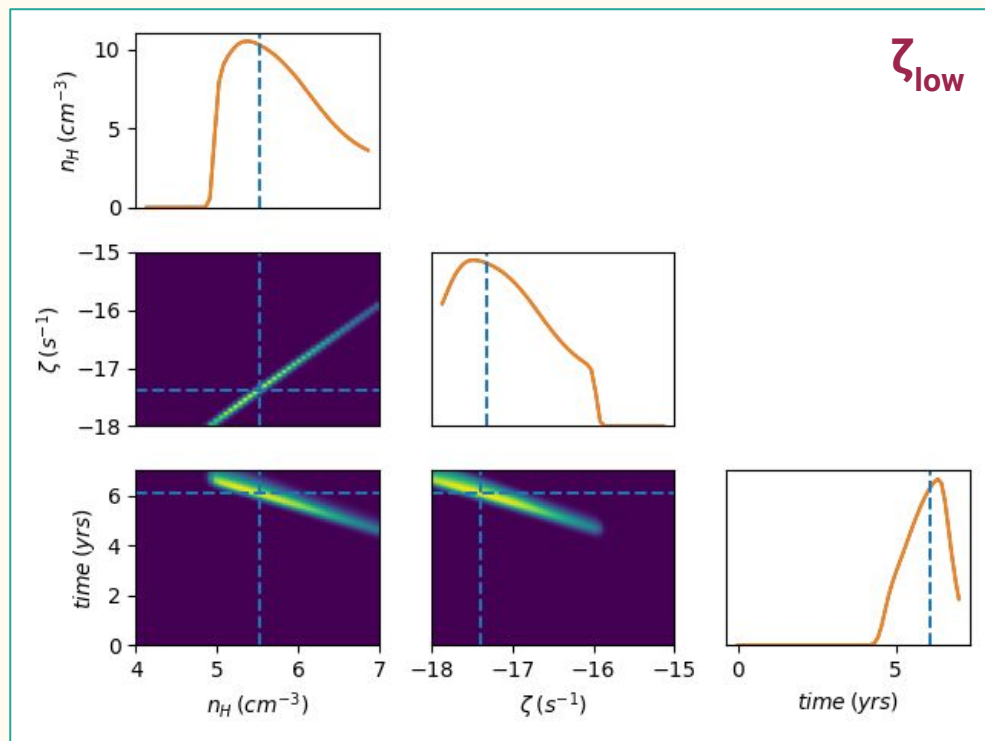

- Exploration on a grid of parameters (size 50x50x64):
  - $n_{\text{H}} \rightarrow$  between  $10^4$  and  $10^7 \text{ cm}^{-3}$
  - $\zeta_{\text{H}_2} \rightarrow$  between  $10^{-18}$  and  $10^{-15} \text{ s}^{-1}$
  - time  $\rightarrow$  between  $\sim 100$  and  $10^7$  years
- Simulated data: as a first attempt
  - for the set of observed molecules
  - for a given value of the uncertainty on the abundances
  - for a given time and  $n_{\text{H}} \rightarrow$  check if we can differentiate two  $\neq \zeta_{\text{H}_2}$  values ( $\zeta_{\text{high}}$  vs  $\zeta_{\text{low}}$ )

⇒ Goal: get the posterior probability distributions of the 3 parameters for a given observation

# Constraining $\zeta_{\text{H}_2}$ with chemistry?

## A first test: likelihood only, no prior

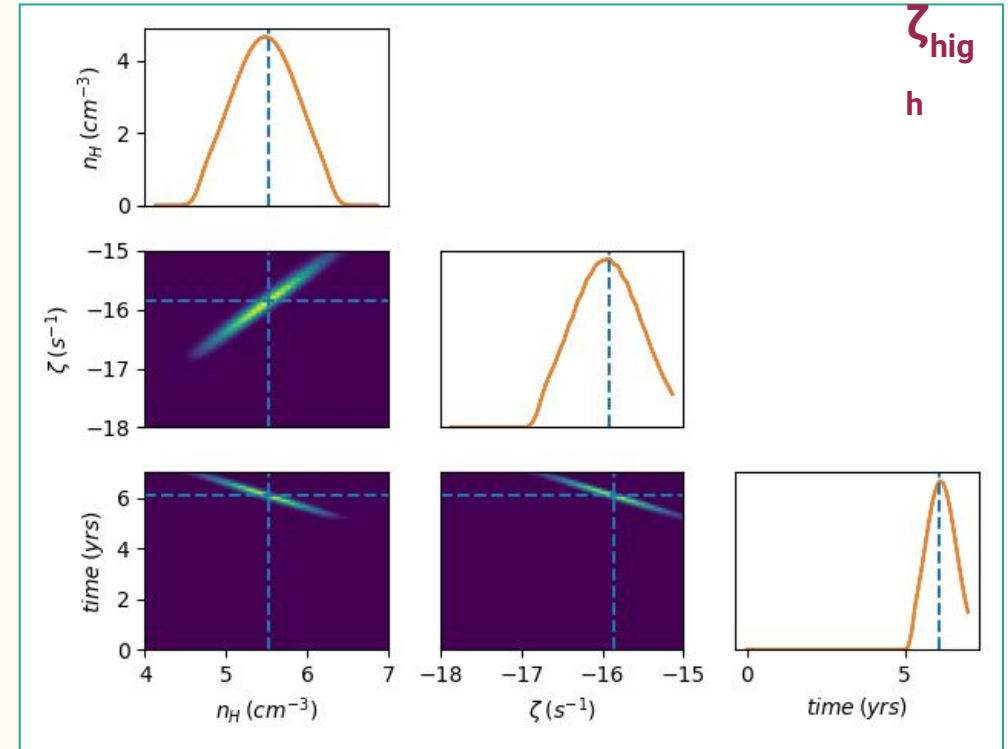

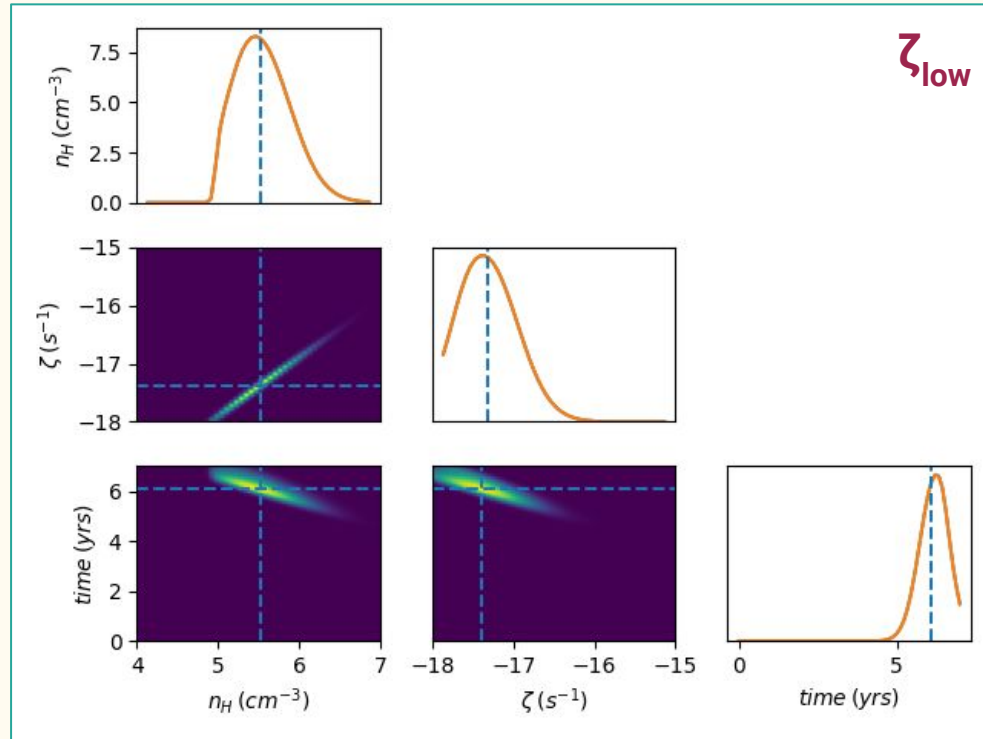

Code developed by Lydie Roosens during her M1 internship at the LAB

→ As it is, we can already roughly discriminate between high and low  $\zeta_{\text{H}_2}$

# Constraining $\zeta_{\text{H}_2}$ with chemistry?

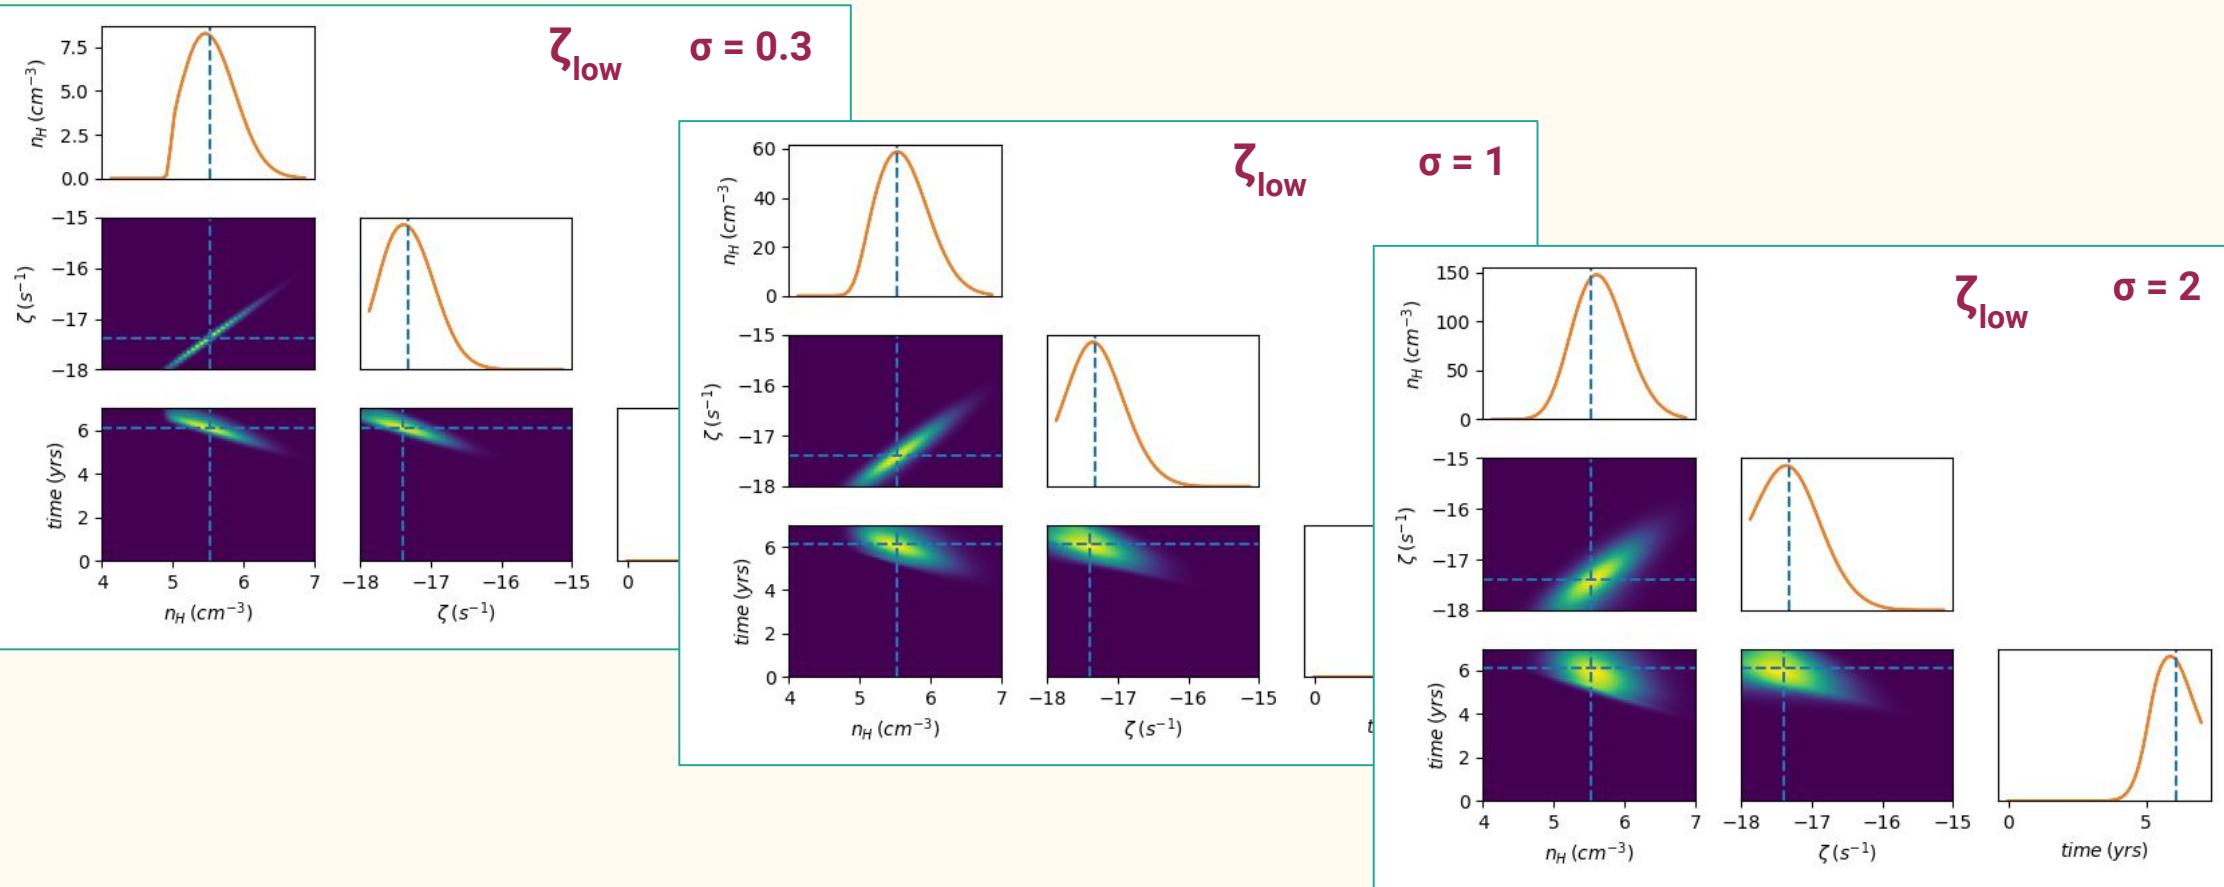

## Adding a prior on $n_{\text{H}}$

→ Adding a prior on the density reduces the uncertainty on the other parameters

# Constraining $\zeta_{\text{H}_2}$ with chemistry?

- We can discriminate high and low  $\zeta_{\text{H}_2}$  when working on simulated data
- Tests with increasing  $\sigma$  still allow us to discriminate  $\zeta_{\text{H}_2}$  (until a factor of  $>100$  on the abundances)

→ Next step: same work on our real observational data

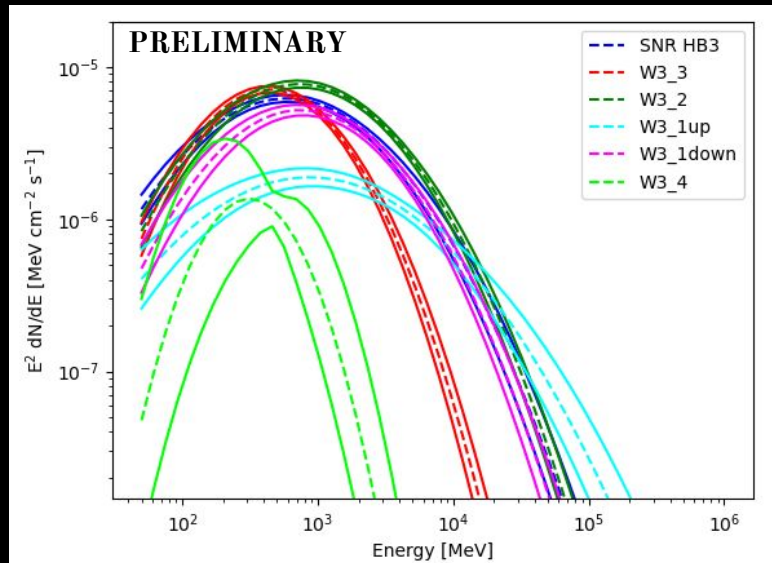

# Gamma-ray astronomy and astrochemistry

## Link between the two parts

- \* Analysis of 14 years of Fermi-LAT data
  - \* Morphological analysis results after multiple tests:
    - o for W3: Dame  $^{12}\text{CO}$  template iteratively divided into 5 parts
    - o for HB3: uniform disk
  - \* The two 30m pointings are in two different parts of W3 : W3\_2 and W3\_3
  - \* These two parts have significantly different gamma-ray spectra, thus different cosmic-ray spectra
- ⇒ we expect to find two different  $\text{H}_2$  cosmic-ray ionization rates!**

# Conclusions

---

- ★ Study of the impact of cosmic-rays on the chemistry of W3 (the molecular cloud interacting with the SNR HB3)
- ★ Observations:
  - Radio data (IRAM 30m and Yebes 40m)
- ★ Methods:
  - Nautilus (chemical modeling)
- ★ Goal: Reproduce the observed molecular column densities with Nautilus to constrain  $\zeta_{\text{H}_2}$  (the  $\text{H}_2$  ionization rate)
  - Tests on a parameter grid ( $n_{\text{H}}$ ,  $\zeta_{\text{H}_2}$ , time)
  - Discriminate high and low  $\zeta_{\text{H}_2}$  with simulated data
- ★ Perspectives:
  - Discriminate high and low  $\zeta_{\text{H}_2}$  on real observational data
  - Link the astrochemistry and gamma-ray studies

**⇒ constrain  $\zeta_{\text{H}_2}$  and understand better the cosmic-rays in the HB3/W3 region**

# BACK-UP

# Methods

## Cosmic-rays related processes in Nautilus (Ruaud et al. 2016, Wakelam et al. 2024)

- \* Photodissociation/ionization with cosmic ray
- \* Gas phase photodissociations/ionizations by secondary UV photons generated by CR
- \* Desorption induced by cosmic-ray stochastic heating
- \* Photodissociations by cosmic rays induced UV photons on grain surface
- \* Photodesorption by UV induced by cosmic rays
- \* Cosmic-ray sputtering (see Wakelam et al. 2021)

# Scientific context

## $\gamma$ -ray astronomy - Cosmic-rays (CRs)

- \*  $\gamma$ -rays = photons with  $E > 100$  keV
- \*  $\gamma$ -ray astronomy  $\rightarrow$  fundamental tool to observe the Universe using deep penetrating  $\gamma$ -ray photons

- \* ~~Image the Universe with CRs~~  $\rightarrow$  CRs are deflected by the magnetic field!

CR ions and electrons can interact with target particles to make  $\gamma$ -rays through secondary nuclear production and bremsstrahlung

- \* A distinctive  $\gamma$ -ray signature of CRs  $\rightarrow$  interactions of CR protons and ions with gas and dust  $\rightarrow$  characteristic  $\pi^0 \rightarrow 2\gamma$  emission feature (Stecker 1971)

$\Rightarrow$  pion-decay bump  $\rightarrow$  uniquely identifies proton acceleration

# Sensitive species to the ionization rate $\zeta$

Table 1: List of the molecules detectable in the Q band whose abundances are strongly dependent on the cosmic-ray rate. Expected detections with peak signal to noise ratio larger than 3 are shown in bold face

	Peak Signal to Noise Ratio		$\frac{\zeta_{CR=10^{-16} s^{-1}}}{\zeta_{CR=10^{-17} s^{-1}}}$ Abundance ratio
	$\zeta_{CR} = 10^{-17} s^{-1}$	$\zeta_{CR} = 10^{-16} s^{-1}$

# Gamma-ray analysis

## Quick method & morphological analysis

Fermi  
(launched  
in 2008)

\* Analysis of 14 years of Fermi-LAT data using Fermipy (vs 6 years of data in a previous analysis by Katagiri et al. 2016)

\* Maximum likelihood method: probability of obtaining the data given an input model of the sources from a region

\* Templates tested to reproduce the gamma-ray emission:

- spatial templates that trace the interstellar matter distribution for W3
- multi-wavelength templates + disks (extension fit) for HB3

\* W3 is 10 times brighter than HB3 → importance of the template choice for W3

\* Morphological analysis results after multiple tests:

- for W3: Dame 12CO template iteratively divided into 5 parts
- for HB3: uniform disk

# Gamma-ray analysis

Spectral analysis: with Dame divided into 5 parts

Comparison between the different parts of W3 and HB3  $\Rightarrow$  they seem different !
